

IN THE UNITED STATES PATENT AND TRADEMARK OFFICE

Serial No.: 10/587,067
Filing Date: November 5, 2008
Applicant: Paul Vermeij
Confirmation No.: 1685
Group Art Unit: 1645
Examiner: Dr. Rodney P. Schwartz
Title: Lawsonia Intracellularis Subunit Vaccine
Attorney Docket: 2004.001 US

DECLARATION UNDER 37 CFR 1.132

Commissioner for Patents
P.O. Box 1450
Alexandria, Virginia 22313-1450

I, Dr. Paul Vermeij, inventor of the invention claimed in the above identified Application, and Applicant therefor, hereby declare:

In the present application it is stated that "...*Lawsonia intracellularis* produces nine novel proteins, each of which is capable, separately or in combination with any of the other of these nine novel proteins, to produce immunity against *Lawsonia intracellularis*. The first of these nine novel proteins will be referred to as the 75 kD protein." (Specification, page 2, lines 15-20).

Particular reference to the 75 kD protein is disclosed in Example 1. "Conclusion: the 75 kD vaccine component could be successfully expressed in large quantities and is indeed clearly recognized by both orally challenged pig anti-*L. intracellularis* serum and by chicken anti-*L. intracellularis* serum." (Specification, page 28, lines 8-10).

To further that the 75 Kd protein performs as an effective protective antigen when administered in a vaccine in which it is the sole *L. intracellularis* antigen, as stated in the Specification and claimed, an experiment was conducted under my supervision in which the 75 kD protein was the sole component in a vaccine.

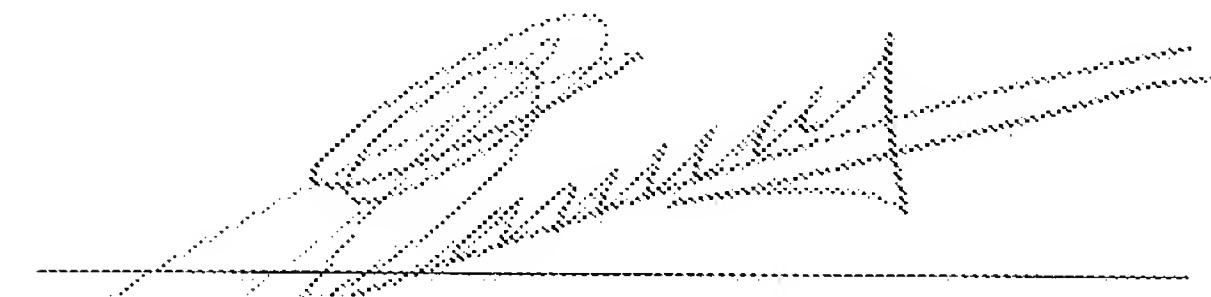

The experiment is described as follows:

6-week-old SPF pigs were used for the experiment. The pigs were allotted to several groups of five pigs each. Group 3 was vaccinated with the 75 KD protein, as currently claimed, and Group 8 was left as an unvaccinated control. The vaccines were formulated in Dihuvac Forte adjuvant (commercially available from Intervet/Schering-Plough Animal Health) and were administered IM in the neck at T=0 and at T=4weeks. At T=6weeks all pigs were challenged orally with homogenized infected mucosa. Subsequently all pigs were observed daily for clinical signs of Porcine Proliferative Enteropathy (PPE). At T=0, 6, 7, 8 and 9weeks, all pigs were weighed and serum blood (for serology IFT test) and faeces (for PCR) were sampled. At T=9 weeks all pigs were euthanized and necropsied. The intestines (ileum and jejunum) were checked macroscopically for *Lawsonia intracellularis* infection, as well as microscopically (immunohistology).

The results are in the attached tables. Table 3 illustrates that the vaccine induced a significant anti-body titre (7.3) compared to the control (1.2). Table 5 clearly shows that the vaccine was able to significantly reduce the shedding of *Lawsonia intracellularis* after challenge. Table 7 indicates that the post-mortem scores of the Ileum are also significantly better than those of the control group (24 vs. 100). Table 8 clearly shows that the vaccinated group histologically scored negative after challenge, whereas the control group scored positive.

These results indicate that the presently claimed subject matter solves the problem of obtaining a protective immune response, which is shown can be achieved using only the 75 kD protein.

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code, and that such willful false statements may jeopardize the validity of the application or any patent issued thereon.

Paul Vermeij
